

Solve $y'' - 4y' + 4y = 0$

Using quick 3.4 method. Guess $y = e^{rt}$ and plug into equation to find $r^2 - 4r + 4 = 0$. Thus $(r - 2)^2 = 0$. Hence $r = 2$. Therefore general solution is $y = c_1 e^{2x} + c_2 x e^{2x}$.

Use LONG 5.2 method (normally use this method only when other shorter methods don't exist) to find solution for values near $x_0 = 0$.

Suppose the solution $y = f(x)$ is analytic at $x_0 = 0$.

That is $f(x) = \sum_{n=0}^{\infty} \frac{f^{(n)}(0)}{n!} (x - 0)^n$ for x near $x_0 = 0$.

Thus there are constants $a_n = \frac{f^{(n)}(0)}{n!}$ such that,

$$f(x) = \sum_{n=0}^{\infty} a_n (x - 0)^n = \sum_{n=0}^{\infty} a_n x^n.$$

Find a recursive formula for the constants of the series solution to $y'' - 4y' + 4y = 0$ near $x_0 = 0$

We will determine these constants a_n by plugging f into the ODE.

$$f(x) = \sum_{n=0}^{\infty} a_n x^n, f'(x) = \sum_{n=1}^{\infty} a_n n x^{n-1}, f''(x) = \sum_{n=2}^{\infty} a_n n(n-1) x^{n-2}.$$

$$\sum_{n=2}^{\infty} a_n n(n-1) x^{n-2} - 4 \sum_{n=1}^{\infty} a_n n x^{n-1} + 4 \sum_{n=0}^{\infty} a_n x^n = 0.$$

$$\sum_{n=0}^{\infty} a_{n+2} (n+2)(n+1) x^n - 4 \sum_{n=0}^{\infty} a_{n+1} (n+1) x^n + 4 \sum_{n=0}^{\infty} a_n x^n = 0.$$

$$\sum_{n=0}^{\infty} [a_{n+2} (n+2)(n+1) - 4a_{n+1} (n+1) + 4a_n] x^n = 0.$$

$$a_{n+2} (n+2)(n+1) - 4a_{n+1} (n+1) + 4a_n = 0.$$

$$a_{n+2} = \frac{4a_{n+1} (n+1) - 4a_n}{(n+2)(n+1)}.$$

Hence the recursive formula (if know previous terms, can determine later terms) is

$$a_{n+2} = 4 \left(\frac{(n+1)a_{n+1} - a_n}{(n+2)(n+1)} \right)$$

Given the recursive formula, $a_{n+2} = 4 \left(\frac{(n+1)a_{n+1} - a_n}{(n+2)(n+1)} \right)$, determine a_n .

Determine formula for a_k by noticing patterns. Note: It is easier to notice patterns if you do NOT simplify too much.

Find the first 6 terms of the series solution

$$n = 0: \quad a_2 = 4 \left(\frac{a_1 - a_0}{(2)(1)} \right)$$

$$n = 1: \quad a_3 = 4 \left(\frac{(2)(4) \left(\frac{a_1 - a_0}{(2)(1)} \right) - a_1}{(3)(2)} \right) = 4 \left(\frac{4(a_1 - a_0) - a_1}{(3)(2)} \right) \\ = 4 \left(\frac{3a_1 - 4a_0}{3!} \right)$$

$$n = 2: \quad a_4 = 4 \left(\frac{3a_3 - a_2}{(4)(3)} \right) = 4 \left(\frac{3(4) \left(\frac{3a_1 - 4a_0}{3!} \right) - 4 \left(\frac{a_1 - a_0}{2!} \right)}{(4)(3)} \right) = 4 \left(\frac{3 \left(\frac{3a_1 - 4a_0}{3!} \right) - \left(\frac{a_1 - a_0}{2!} \right)}{3} \right) \\ = 4 \left(\frac{\left(\frac{3a_1 - 4a_0}{2!} \right) - \left(\frac{a_1 - a_0}{2!} \right)}{3} \right) = 4 \left(\frac{(3a_1 - 4a_0) - (a_1 - a_0)}{3!} \right) = 4 \left(\frac{2a_1 - 3a_0}{(3)!} \right)$$

$$n = 3: \quad a_5 = 4 \left(\frac{(4)a_4 - a_3}{(5)(4)} \right) = 4 \left(\frac{(4)4 \left(\frac{2a_1 - 3a_0}{3!} \right) - 4 \left(\frac{3a_1 - 4a_0}{3!} \right)}{(5)(4)} \right) \\ = 4 \left(\frac{4 \left(\frac{2a_1 - 3a_0}{3!} \right) - \left(\frac{3a_1 - 4a_0}{3!} \right)}{5} \right) = 4 \left(\frac{4(2a_1 - 3a_0) - (3a_1 - 4a_0)}{5(3!)} \right) = 4 \left(\frac{5a_1 - 8a_0}{5(3!)} \right)$$

$$f(x) \sim a_0 + a_1 x + 4 \left(\frac{a_1 - a_0}{2!} \right) x^2 + 4 \left(\frac{3a_1 - 4a_0}{3!} \right) x^3 + 4 \left(\frac{2a_1 - 3a_0}{(3)!} \right) x^4 + 4 \left(\frac{5a_1 - 8a_0}{5(3!)} \right) x^5$$

Recall $f(x) = a_0 \phi_0(x) + a_1 \phi_1(x)$ for linearly independent solutions ϕ_0 and ϕ_1 to equation $y'' - 4y' + 4y = 0$.

Find the first 5 terms in each of the 2 solns $y = \phi_0(x)$ and $y = \phi_1(x)$

$$\phi_0 \sim 1 + 4 \left(\frac{-1}{2!} \right) x^2 + 4 \left(\frac{-4}{3!} \right) x^3 + 4 \left(\frac{-3}{(3)!} \right) x^4 + 4 \left(\frac{-8}{5(3!)} \right) x^5$$

$$\phi_1 \sim x + 4 \left(\frac{1}{2!} \right) x^2 + 4 \left(\frac{3}{3!} \right) x^3 + 4 \left(\frac{2}{(3)!} \right) x^4 + 4 \left(\frac{5}{5(3!)} \right) x^5$$

$$n = 0: \quad a_2 = 4 \left(\frac{a_1 - a_0}{(2)(1)} \right) = 2 \left(\frac{2a_1 - 2a_0}{2!} \right)$$

$$n = 1: \quad a_3 = 4 \left(\frac{3a_1 - 4a_0}{3!} \right) = 2^2 \left(\frac{3a_1 - 4a_0}{3!} \right)$$

$$n = 2: \quad a_4 = 4 \left(\frac{2a_1 - 3a_0}{3!} \right) = 16 \left(\frac{2a_1 - 3a_0}{4!} \right) = 8 \left(\frac{4a_1 - 6a_0}{4!} \right) = 2^3 \left(\frac{4a_1 - 6a_0}{4!} \right)$$

$$n = 3: \quad a_5 = 4 \left(\frac{5a_1 - 8a_0}{5(3!)} \right) = 16 \left(\frac{5a_1 - 8a_0}{5!} \right) = 2^4 \left(\frac{5a_1 - 8a_0}{5!} \right)$$

Hence it appears $a_k = \frac{2^{k-1}(ka_1 - 2(k-1)a_0)}{k!}$

Prove that if $a_{n+2} = 4 \left(\frac{(n+1)a_{n+1} - a_n}{(n+2)(n+1)} \right)$, **then** $a_k = \frac{2^{k-1}(ka_1 - 2(k-1)a_0)}{k!}$

Need to prove $a_k = \frac{2^{k-1}(ka_1 - 2(k-1)a_0)}{k!}$ for $k \geq 0$

Given: $a_{n+2} = 4 \left(\frac{(n+1)a_{n+1} - a_n}{(n+2)(n+1)} \right)$ for $n \geq 2$,

Proof by induction on k .

Suppose $k = 0$. Then $\frac{2^{0-1}(0(a_1) - 2(-1)a_0)}{0!} = \frac{1}{2}(2a_0) = a_0$

Suppose $k = 1$. Then $\frac{2^{1-1}(1(a_1) - 2(1-1)a_0)}{1!} = a_1$

Suppose $a_k = \frac{2^{k-1}(ka_1 - 2(k-1)a_0)}{k!}$ for $k = n, n+1$

Thus $a_n = \frac{2^{n-1}(na_1 - 2(n-1)a_0)}{n!}$ and $a_{n+1} = \frac{2^n((n+1)a_1 - 2na_0)}{(n+1)!}$

Claim: $a_{n+2} = \frac{2^{n+1}((n+2)a_1 - 2(n+1)a_0)}{(n+2)!}$

$$\begin{aligned} a_{n+2} &= 4 \left(\frac{(n+1)a_{n+1} - a_n}{(n+2)(n+1)} \right) = 4 \left(\frac{(n+1) \left[\frac{2^n((n+1)a_1 - 2na_0)}{(n+1)!} \right] - \left[\frac{2^{n-1}(na_1 - 2(n-1)a_0)}{n!} \right]}{(n+2)(n+1)} \right) \\ &= 4 \left(\frac{\left[\frac{2^n((n+1)a_1 - 2na_0)}{n!} \right] - \left[\frac{2^{n-1}(na_1 - 2(n-1)a_0)}{n!} \right]}{(n+2)(n+1)} \right) \\ &= 4(2)^{n-1} \left(\frac{[2((n+1)a_1 - 2na_0)] - [na_1 - 2(n-1)a_0]}{n!(n+2)(n+1)} \right) \\ &= 2^{n+1} \left(\frac{2(n+1)a_1 - 4na_0 - na_1 + 2(n-1)a_0}{n!(n+2)(n+1)} \right) = 2^{n+1} \left(\frac{(n+2)a_1 - 2(n+1)a_0}{(n+2)!} \right) \end{aligned}$$

$$\begin{aligned} \text{Thus } f(x) &= \sum_{n=0}^{\infty} \frac{2^{n-1}(na_1 - 2(n-1)a_0)}{n!} x^n \\ &= a_1 \sum_{n=0}^{\infty} \frac{2^{n-1}(n)}{n!} x^n - 2a_0 \sum_{n=0}^{\infty} \frac{2^{n-1}(n-1)}{n!} x^n \\ &= a_0(-2) \sum_{n=0}^{\infty} \frac{2^{n-1}(n-1)}{n!} x^n + a_1 \sum_{n=1}^{\infty} \frac{2^{n-1}}{(n-1)!} x^n \end{aligned}$$

if these two series converge.

For what values of x does $\sum_{n=0}^{\infty} \frac{(n-1)2^{n-1}}{n!} x^n$ converge

Ratio test: Suppose we have the series $\sum b_n$. Let $L = \lim_{n \rightarrow \infty} \left| \frac{b_{n+1}}{b_n} \right|$

Then, if $L < 1$, the series is absolutely convergent (and hence convergent).

If $L > 1$, the series is divergent.

If $L = 1$, the series may be divergent, conditionally convergent, or absolutely convergent.

$$\begin{aligned} \lim_{n \rightarrow \infty} \left| \frac{\frac{n2^n}{(n+1)!} x^{n+1}}{\frac{(n-1)2^{n-1}}{n!} x^n} \right| &= \lim_{n \rightarrow \infty} \left| \frac{2nx}{(n+1)(n-1)} \right| \\ &= 2x \lim_{n \rightarrow \infty} \left| \frac{n}{(n+1)(n-1)} \right| = 0 \end{aligned}$$

Hence the series converges for all x

For what values of x does $\sum_{n=1}^{\infty} \frac{2^{n-1}}{(n-1)!} x^n$ converge

$$\lim_{n \rightarrow \infty} \left| \frac{\frac{2^n}{n!} x^{n+1}}{\frac{2^{n-1}}{(n-1)!} x^n} \right| = \lim_{n \rightarrow \infty} \left| \frac{2x}{n} \right| = 2x \lim_{n \rightarrow \infty} \left| \frac{1}{n} \right| = 0$$

Hence the series converges for all x

Thus the solution is

$$f(x) = a_0(-2) \sum_{n=0}^{\infty} \frac{2^{n-1}(n-1)}{n!} x^n + a_1 \sum_{n=1}^{\infty} \frac{2^{n-1}}{(n-1)!} x^n$$

and the domain is all real numbers.

I.e., the general solution is $f(x) = a_0 \phi_0(x) + a_1 \phi_1(x)$

$$\text{where } \phi_0(x) = (-2) \sum_{n=0}^{\infty} \frac{2^{n-1}(n-1)}{n!} x^n \text{ and } \phi_1(x) = \sum_{n=1}^{\infty} \frac{2^{n-1}}{(n-1)!} x^n$$

Note we could have replaced the constant a_0 with $-2a_0$, but the a_i 's have meaning: $a_n = \frac{f^{(n)}(0)}{n!}$. Thus our initial values are $a_0 = f(0)$ and $a_1 = f'(0)$

In general, to determine if there is a unique solution to the IVP, $y'' - 4y' + 4y = 0$, $y(x_0) = y_0$, $y'(x_0) = y_1$, we solve for unknowns a_0 and a_1 .

$$\begin{aligned} y(x_0) &= a_0\phi_0(x_0) + a_1\phi_1(x_0) \\ y'(x_0) &= a_0\phi'_0(x_0) + a_1\phi'_1(x_0) \end{aligned}$$

Note that the above system of two equations has a unique solution for the two unknowns a_0 and a_1 if and only if $\det \begin{pmatrix} \phi_0(x_0) & \phi_1(x_0) \\ \phi'_0(x_0) & \phi'_1(x_0) \end{pmatrix} \neq 0$

In other words the IVP has a unique solution iff the Wronskian of ϕ_0 and ϕ_1 evaluated at x_0 is not zero. Recall that by theorem, this also implies that ϕ_0 and ϕ_1 are linearly independent and hence the general solution is $y = a_0\phi_0(x) + a_1\phi_1(x)$ by theorem.

Show that $\phi_0(x) = (-2)\sum_{n=0}^{\infty} \frac{2^{n-1}((n-1))}{n!}x^n$ and $\phi_1(x) = \sum_{n=1}^{\infty} \frac{2^{n-1}}{(n-1)!}x^n$ are linearly independent by calculating the Wronskian of these two functions evaluated at $x_0 = 0$.

$$W(\phi_1, \phi_2)(x) = \begin{pmatrix} \phi_1(x) & \phi_2(x) \\ \phi'_1(x) & \phi'_2(x) \end{pmatrix} = \begin{pmatrix} (-2)\sum_{n=0}^{\infty} \frac{2^{n-1}(n-1)}{n!}x^n & \sum_{n=1}^{\infty} \frac{2^{n-1}}{(n-1)!}x^n \\ (-2)\sum_{n=1}^{\infty} \frac{2^{n-1}(n-1)}{(n-1)!x^{n-1}} & \sum_{n=1}^{\infty} \frac{n2^{n-1}}{(n-1)!}x^{n-1} \end{pmatrix}$$

$$W(\phi_1, \phi_2)(0) = \begin{pmatrix} (-2)2^{0-1}(-1) & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = 1 \neq 0$$

Hence $\phi_0(x) = (-2)\sum_{n=0}^{\infty} \frac{2^{n-1}((n-1))}{n!}x^n$ and $\phi_1(x) = \sum_{n=1}^{\infty} \frac{2^{n-1}}{(n-1)!}x^n$ are linearly independent

When possible identify the functions giving the series solutions. Recall that by Taylor's theorem and the ratio test, $e^{2x} = \sum_{n=0}^{\infty} \frac{f^{(n)}(x)}{n!}x^n = \sum_{n=0}^{\infty} \frac{2^n}{n!}x^n$ for all x .

$$\begin{aligned} f(x) &= a_1\sum_{n=0}^{\infty} \frac{n2^{n-1}}{n!}x^n - 2a_0\sum_{n=0}^{\infty} \frac{2^{n-1}(n-1)}{n!}x^n \\ &= a_1\sum_{n=0}^{\infty} \frac{n2^{n-1}}{n!}x^n - 2a_0\sum_{n=0}^{\infty} \frac{n2^{n-1}}{n!}x^n + 2a_0\sum_{n=0}^{\infty} \frac{2^{n-1}}{n!}x^n \\ &= (a_1 - 2a_0)\sum_{n=0}^{\infty} \frac{n2^{n-1}}{n!}x^n + a_0\sum_{n=0}^{\infty} \frac{2^n}{n!}x^n \end{aligned}$$

$$\begin{aligned}
&= (a_1 - 2a_0)x \sum_{n=1}^{\infty} \frac{2^{n-1}}{(n-1)!} x^{n-1} + a_0 \sum_{n=0}^{\infty} \frac{2^n}{n!} x^n \\
&= (a_1 - 2a_0)x \sum_{n=0}^{\infty} \frac{2^n}{n!} x^n + a_0 \sum_{n=0}^{\infty} \frac{2^n}{n!} x^n \\
&= (a_1 - 2a_0)x e^{2x} + a_0 e^{2x}
\end{aligned}$$

Note we have recovered the solution we found using the 3.4 method.

Note a power series solutions exists in a neighborhood of x_0 when the solution is analytic at x_0 . I.e, the solution is of the form $y = \sum_{n=0}^{\infty} a_n (x - x_0)^n$ where this series has a nonzero radius of convergence about x_0 .

When do we know an analytic solution exists? I.e, when is this method guaranteed to work?

Special case: $P(x)y'' + Q(x)y' + R(x)y = 0$

Then $y''(x) = -\frac{Q}{P}y' - \frac{R}{P}y$

Definition: The point x_0 is an *ordinary point* of the ODE,

$$P(x)y'' + Q(x)y' + R(x)y = 0$$

if $\frac{Q}{P}$ and $\frac{R}{P}$ are analytic at x_0 .

Theorem 5.3.1: If x_0 is an ordinary point of the ODE $P(x)y'' + Q(x)y' + R(x)y = 0$, then the general solution to this ODE is

$$y = \sum_{n=1}^{\infty} a_n (x - x_0)^n = a_0 \phi_0(x) + a_1 \phi_1(x)$$

where ϕ_i are power series solutions that are analytic at x_0 . The solutions ϕ_0, ϕ_1 form a fundamental set of solutions. The radius of convergence for each of these series solutions is at least as large as the minimum radii of convergence of the series for $\frac{Q}{P}$ and $\frac{R}{P}$.

Theorem: If P and Q are polynomial functions, then $y = Q(x)/P(x)$ is analytic at x_0 if and only if $P(x_0) \neq 0$. Moreover if Q/P is reduced, the radius of convergence of $Q(x)/P(x) = \min\{\|x_0 - x\| \mid x \in \mathbf{C}, P(x) = 0\}$ where $\|x_0 - x\| = \text{distance from } x_0 \text{ to } x \text{ in the complex plane}$.
