# Minimum Cut Problem

The input:

- ▶ A directed graph  $G = (V, E)$
- ▶ Two special vertices: **source**  $s$  and **target**  $t$
- ▶ A function  $c : E \rightarrow \mathbb{R}_{\geq 0}$ , that assigns a **capacity** to each edge.

# Minimum Cut Problem

# Minimum Cut Problem

- ▶ A  $(s, t)$ -cut is an ordered pair  $(S, T)$  such that
  1.  $S$  and  $T$  partition  $V$
  2.  $s \in S$  and  $t \in T$
- ▶  $\text{Cap}(S, T)$ , the **capacity** of cut  $(S, T)$ , is the sum of the capacities of all edges **crossing** the cut (from  $S$  to  $T$ ):

$$\sum_{u \in S, v \in T} c(u, v)$$

For notational convenience, we pretend  $c(u, v) = 0$  if  $(u, v) \notin E$ .

## Cut: Example 1

$$\text{Capacity} = 2 + 6 + 20 = 28$$

## Cut: Example 2

$$\text{Capacity} = 2 + 12 + 4 + 10 = 28$$

# Minimum Cut Problem

- ▶ The goal is to find an  $(s, t)$ -cut with minimum capacity
- ▶ Such a cut is known as the minimum capacity cut, or a minimum cut
- ▶ Removing edges crossing a minimum cut gives cheapest way of ensuring  $s$  cannot reach  $t$ .

# Maximum Flow Problem

- ▶ Input same as in minimum cut problem
- ▶ An  $(s, t)$ -flow is a function  $f : E \rightarrow \mathbb{R}_{\geq 0}$  that satisfies the following **conservation constraint** at each vertex  $v$  other than the source  $s$  and sink  $t$ :

$$\sum_u f(u, v) = \sum_w f(v, w)$$

- ▶ That is, the total flow into  $v$  is the total flow out of  $v$ .
- ▶  $f(u, v)$  is referred to as the flow on  $(u, v)$ .

# Flow Example

# Value of Flow

- ▶ The **value** of flow  $f$ , denoted  $|f|$ , is

$$|f| := \sum_w f(s, w) - \sum_u f(u, s).$$

- ▶ That is,  $|f|$  is the net flow out of the source  $s$ .

# Flow Example

Value of flow =  $2 + 6 + 12 = 20$

# Feasible Flow

- ▶ A flow  $f$  is **feasible** if for each edge  $(u, v)$ , flow on edge is at most its capacity:

$$f(u, v) \leq c(u, v)$$

- ▶ This is called the **capacity constraint**

# Maximum Flow Problem

- ▶ The input is directed graph  $G$  along with edge capacities, source  $s$  and sink  $t$ .
- ▶ The goal is to find a feasible flow  $f$  that maximizes the value  $|f|$ . Such a maximizing flow is called a **maximum flow**

# Flow Example

Value of flow =  $2 + 6 + 12 = 20$

## Source vs. Sink

Let us use some notation for the net flow out of  $v$ :

$$\partial f(v) := \sum_w f(v, w) - \sum_u f(u, v)$$

We have:

$$0 = \sum_v \partial f(v) = \partial f(s) + \partial f(t)$$

- ▶ The first equality follows because any edge  $(u, v)$  contributes  $f(u, v)$  to  $\partial f(u)$  and  $-f(u, v)$  to  $\partial f(v)$ .
- ▶ The second equality uses flow conservation.

## Source vs. Sink

- ▶ Thus,  $|f| = \partial f(s) = -\partial f(t)$
- ▶ That is, net flow out of  $s$  equals net flow into  $t$ . We will see a generalization of this idea a bit later.

# Towards a Maximum Flow Algorithm

Value of flow = 18

# Towards a Maximum Flow Algorithm

Value of flow = 18

Can we improve on this flow?

Value of flow = 20

# Residual Network

Suppose we have a flow  $f$  that is feasible. Also assume that in the network  $G$ , for every pair of vertices  $u$  and  $v$ , at most one of  $(u, v)$  and  $(v, u)$  is an edge in  $G$ .

- ▶ For each  $(u, v) \in E$ , let
  1.  $c_f(u, v) := c(u, v) - f(u, v)$
  2.  $c_f(v, u) := f(u, v)$
- ▶ We call  $c_f(e)$  the **residual capacity** of  $e$ .
- ▶ The **residual network**  $G_f$  consists of all edges whose residual capacity is strictly positive.

# Residual Network

# Ford-Fulkerson Algorithm

- ▶ Initialize  $f$  to the zero flow
- ▶ While (there is a path from  $s$  to  $t$  in residual  $G_f$ )
  - ▶ Let  $\pi$  be any (simple) path from  $s$  to  $t$  in  $G_f$ .
  - ▶ Augment  $f$  using  $\pi$ , as described below.

# Flow Augmentation

# Flow Augmentation

Value of flow = 20

# Augmented Flow

Value of flow = 22

# Flow Augmentation

Augmenting flow  $f$  using path  $\pi$  in residual network  $G_f$ :

- ▶ Let  $\mu > 0$  be the minimum residual capacity of an edge in  $\pi$ .
- ▶ For each edge  $(u, v) \in G$ 
  - ▶  $f'(u, v) \leftarrow f(u, v) + \mu$  if  $(u, v)$  is on  $\pi$
  - ▶  $f'(u, v) \leftarrow f(u, v) - \mu$  if  $(v, u)$  is on  $\pi$ .
  - ▶  $f'(u, v) \leftarrow f(u, v)$  otherwise.
- ▶  $f \leftarrow f'$ .

Is this flow optimal?

Value of flow = 22

## Algorithm Terminates: No path in residual network

## Algorithm Terminates: Reachability in residual network

# Flow vs. Cut

flow value = 22, cut capacity = 22
