

SUBNORMALITY AND 2-HYPONORMALITY FOR TOEPLITZ OPERATORS

Raúl E. Curto,¹ Sang Hoon Lee and Woo Young Lee²

In this article we provide an example of a Toeplitz operator which is 2-hyponormal but not subnormal, and we consider 2-hyponormal Toeplitz operators with finite rank self-commutators.

The present article concerns the gap between subnormality and 2-hyponormality for Toeplitz operators. We begin with a brief survey of research related to P.R. Halmos's Problem 5 (cf. [Ha1],[Ha2]):

(Prob 5) Is every subnormal Toeplitz operator either normal or analytic ?

As we know, (Prob 5) was answered in the negative by C. Cowen and J. Long [CoL]. Directly connected with it is the following problem:

(0.1) Which Toeplitz operators are subnormal ?

Let \mathcal{H} and \mathcal{K} be complex Hilbert spaces, let $\mathcal{L}(\mathcal{H}, \mathcal{K})$ be the set of bounded linear operators from \mathcal{H} to \mathcal{K} and write $\mathcal{L}(\mathcal{H}) := \mathcal{L}(\mathcal{H}, \mathcal{H})$. An operator $T \in \mathcal{L}(\mathcal{H})$ is said to be normal if $T^*T = TT^*$, hyponormal if $T^*T \geq TT^*$, and subnormal if $T = N|_{\mathcal{H}}$, where N is normal on some Hilbert space $\mathcal{K} \supseteq \mathcal{H}$. If T is subnormal then T is also hyponormal. Recall that the Hilbert space $L^2(\mathbb{T})$ has a canonical orthonormal basis given by the trigonometric functions $e_n(z) = z^n$, for all $n \in \mathbb{Z}$, and that the Hardy space $H^2(\mathbb{T})$ is the closed linear span of $\{e_n : n = 0, 1, \dots\}$. An element $f \in L^2(\mathbb{T})$ is said to be analytic if $f \in H^2(\mathbb{T})$, and co-analytic if $f \in L^2(\mathbb{T}) \ominus H^2(\mathbb{T})$. If P denotes the orthogonal projection from $L^2(\mathbb{T})$ to $H^2(\mathbb{T})$, then for every $\varphi \in L^\infty(\mathbb{T})$ the operators T_φ and H_φ on $H^2(\mathbb{T})$ defined by

$$T_\varphi g := P(\varphi g) \quad \text{and} \quad H_\varphi(g) := (I - P)(\varphi g) \quad (g \in H^2(\mathbb{T}))$$

are called the *Toeplitz operator* and the *Hankel operator*, respectively, with symbol φ .

(Prob 5) has been answered in the affirmative for *trigonometric* Toeplitz operators [ItW], and for *quasinormal* Toeplitz operators [AIW]. In 1976, M. B. Abrahamse [Abr] gave a general sufficient condition for the answer to (Prob 5) to be affirmative.

Theorem 1 ([Abr]). *If*

- (i) T_φ is hyponormal;
- (ii) φ or $\bar{\varphi}$ is of bounded type (i.e., φ or $\bar{\varphi}$ is a quotient of two analytic functions);
- (iii) $\ker[T_\varphi^*, T_\varphi]$ is invariant for T_φ ,

then T_φ is normal or analytic.

Since $\ker[T^*, T]$ is invariant for every subnormal operator T , Theorem 1 answers (Prob 5) affirmatively when φ or $\bar{\varphi}$ is of bounded type. Also, in [Abr], Abrahamse proposed the following question, as a strategy to answer (Prob 5):

(Abr) Is the Bergman shift unitarily equivalent to a Toeplitz operator ?

To study this question, recall that given a bounded sequence of positive numbers $\alpha : \alpha_0, \alpha_1, \dots$ (called *weights*), the (*unilateral*) *weighted shift* W_α associated with α is the operator on $\ell^2(\mathbb{Z}_+)$ defined by $W_\alpha e_n := \alpha_n e_{n+1}$ for all $n \geq 0$, where $\{e_n\}_{n=0}^\infty$ is the canonical orthonormal basis for ℓ^2 . It is straightforward to check that W_α can never be *normal*, and that W_α is *hyponormal* if and only if $\alpha_n \leq \alpha_{n+1}$ for all $n \geq 0$. The Bergman shift is a weighted shift W_α with weights $\alpha := \left\{ \sqrt{\frac{n}{n+1}} \right\}_{n=1}^\infty$; it is well known that the Bergman shift is subnormal. In 1983, S. Sun [Sun] showed that if a Toeplitz operator T_φ is unitarily equivalent to a hyponormal weighted shift W_α with weight sequence α , then α must be of the form

$$(1.1) \quad \alpha = \left\{ (1 - \beta^{2n+2})^{\frac{1}{2}} \|T_\varphi\| \right\}_{n=0}^\infty$$

for some β ($0 < \beta < 1$), thus answering (Abr) in the negative. Cowen and Long [CoL] showed that a unilateral weighted shift with weight sequence of the form (1.1) must be subnormal (see also [Fa]). Consequently, we have:

Theorem 2 ([Sun], [Cow2]). *Every hyponormal Toeplitz operator which is unitarily equivalent to a weighted shift must be subnormal.*

Finally, in 1984 Cowen and Long [CoL] constructed a symbol φ for which T_φ is unitarily equivalent to a weighted shift with weight sequence (1.1). This helped answer (Prob 5) in the negative.

Theorem 3 ([CoL],[Cow2]). *Let $0 < \alpha < 1$ and let ψ be a conformal map of the unit disk onto the interior of the ellipse with vertices $\pm(1+\alpha)i$ and passing through $\pm(1-\alpha)$. If $\varphi = (1-\alpha^2)^{-1}(\psi + \alpha\bar{\psi})$, then T_φ is a weighted shift with weight sequence $\alpha_n = (1-\alpha^{2n+2})^{-\frac{1}{2}}$. Therefore, T_φ is subnormal but neither normal nor analytic. In particular, φ is not of bounded type.*

On the other hand, the Bram–Halmos criterion for subnormality states that an operator T is subnormal if and only if

$$\sum_{i,j} (T^i x_j, T^j x_i) \geq 0$$

for all finite collections $x_0, x_1, \dots, x_k \in \mathcal{H}$ ([Bra],[Con, II.1.9]). It is easy to see that this is equivalent to the following positivity test:

$$(3.1) \quad \begin{pmatrix} I & T^* & \dots & T^{*k} \\ T & T^*T & \dots & T^{*k}T \\ \vdots & \vdots & \ddots & \vdots \\ T^k & T^*T^k & \dots & T^{*k}T^k \end{pmatrix} \geq 0 \quad (\text{all } k \geq 1).$$

Condition (3.1) provides a measure of the gap between hyponormality and subnormality. In fact, the positivity condition (3.1) for $k = 1$ is equivalent to the hyponormality of T , while subnormality requires the validity of (3.1) for all k . If we denote by $[A, B] := AB - BA$ the commutator of two operators A and B , and if we define T to be k -hyponormal whenever the $k \times k$ operator matrix

$$(3.2) \quad M_k(T) := ([T^{*j}, T^i])_{i,j=1}^k$$

is positive, or equivalently, the $(k + 1) \times (k + 1)$ operator matrix in (3.1) is positive (via the operator version of Choleski's Algorithm), then the Bram–Halmos criterion can be rephrased as saying that T is subnormal if and only if T is k -hyponormal for every $k \geq 1$ ([CMX]). It is then natural to try to understand the gap between k -hyponormality and subnormality for Toeplitz operators. In [CuL1] and [CuL3], as a first inquiry in this line of thought the following question was raised.

Question A. *Is every 2-hyponormal Toeplitz operator subnormal?*

In [CuL1], the following was shown: *Every trigonometric Toeplitz operator whose square is hyponormal must be normal or analytic. Hence, in particular, every 2-hyponormal trigonometric Toeplitz operator is subnormal.* We can extend this result.

Theorem 4 ([CuL3, Corollary 6]). *If T_φ is 2-hyponormal and if φ or $\bar{\varphi}$ is of bounded type then T_φ is normal or analytic, so that in particular T_φ is subnormal.*

Proof. It is known (cf. [CuL2]) that if $T \in \mathcal{L}(\mathcal{H})$ is 2-hyponormal then

$$(4.1) \quad T(\ker [T^*, T]) \subseteq \ker [T^*, T].$$

Thus the result follows at once from Theorem 1. □

We now answer Question A in the negative: there is a gap between 2-hyponormality and subnormality for Toeplitz operators. We first establish a theorem which provides an example of a non-weighted shift which is 2-hyponormal but not subnormal.

Theorem 5. For $0 < \alpha < 1$, let $T \equiv W_\beta$ be the weighted shift with weight sequence $\beta = \{\beta_n\}_{n=0}^\infty$ with

$$\beta_n := \left(\sum_{j=0}^n \alpha^{2j} \right)^{\frac{1}{2}}.$$

If $S_\lambda := T + \lambda T^*$ ($\lambda \in \mathbb{C}$), then

- (i) S_λ is hyponormal if and only if $|\lambda| \leq 1$.
- (ii) S_λ is subnormal if and only if $\lambda = 0$ or $|\lambda| = \alpha^k$ for some $k = 0, 1, 2, \dots$.
- (iii) S_λ is 2-hyponormal if and only if $|\lambda| = 1$ or $|\lambda| \leq \alpha$.

Proof. The statements (i) and (ii) are known from [Cow1, Theorem 2.3]. Thus it suffices to focus on the assertion (iii). Since $T + \lambda T^*$ is unitarily equivalent to $e^{\frac{i\theta}{2}}(T + |\lambda|T^*)$ with $|\lambda| = \lambda e^{-i\theta}$ (cf. [Cow1, Lemma 2.1]), it follows that $T + \lambda T^*$ is 2-hyponormal if and only if $T + |\lambda|T^*$ is 2-hyponormal. Thus we may assume $\lambda \geq 0$. If $\lambda = 0, 1$, then evidently S_λ is 2-hyponormal because T is subnormal (cf. [CoL]). Thus, in view of (i), we assume $0 < \lambda < 1$. A straightforward calculation shows that

$$\begin{aligned} M_2(S_\lambda) &\equiv \begin{pmatrix} [S_\lambda^*, S_\lambda] & [S_\lambda^{*2}, S_\lambda] \\ [S_\lambda^*, S_\lambda^2] & [S_\lambda^{*2}, S_\lambda^2] \end{pmatrix} \\ (5.1) \quad &=: (1 - \lambda^2) \begin{pmatrix} A & B \\ B^* & C \end{pmatrix}, \end{aligned}$$

where

$$(5.2) \quad \begin{cases} A &= [T^*, T] \\ B &= [T^{*2}, T] + \lambda [T^*, T^2] \\ C &= (1 + \lambda^2)[T^{*2}, T^2] + \lambda ([T^{*3}, T] + [T^*, T^3] + T^*[T^*, T]T^* + T[T^*, T]T). \end{cases}$$

By (3.2), S_λ is 2-hyponormal if and only if $M_2(S_\lambda) \geq 0$. Recall now Smul'jan's Theorem ([Smu], [CuF, Proposition 2.2]), which states that if

$$(5.3) \quad M := \begin{pmatrix} A & B \\ B^* & C \end{pmatrix} : \begin{pmatrix} \mathcal{H}_1 \\ \mathcal{H}_2 \end{pmatrix} \longrightarrow \begin{pmatrix} \mathcal{H}_1 \\ \mathcal{H}_2 \end{pmatrix},$$

if $A \geq 0$, and if $B = A^{\frac{1}{2}}V$ for some $V : \mathcal{H}_2 \rightarrow \mathcal{H}_1 \ominus N(A)$, then $M \geq 0$ if and only if $C \geq V^*V$. Now apply this result to (5.1). We first argue that in (5.2),

$$(5.4) \quad B := [T^{*2}, T] + \lambda [T^*, T^2] = (1 + \alpha^2) [T^*, T] \left(\frac{\lambda}{\alpha^2} T + T^* \right).$$

To see this, observe that $[T^*, T^2]$ and $[T^*, T]T$ are both unilateral weighted shifts, so it suffices to check the $(n+1, n)$ -entries:

$$([T^*, T^2]e_n, e_{n+1}) = \beta_n(\beta_{n+1}^2 - \beta_{n-1}^2) = \beta_n(\alpha^{2n+2} + \alpha^{2n})$$

and

$$([T^*, T]Te_n, e_{n+1}) = \beta_n(\beta_{n+1}^2 - \beta_n^2) = \beta_n\alpha^{2n+2},$$

which implies that

$$\begin{aligned} (\lambda[T^*, T^2]e_n, e_{n+1}) &= \lambda\beta_n(\alpha^{2n+2} + \alpha^{2n}) \\ &= \lambda\beta_n\left(1 + \frac{1}{\alpha^2}\right)\alpha^{2n+2} \\ &= \left(\lambda\left(1 + \frac{1}{\alpha^2}\right)\right)[T^*, T]Te_n, e_{n+1}), \end{aligned}$$

giving $\lambda[T^*, T^2] = (1 + \alpha^2)\frac{\lambda}{\alpha^2}[T^*, T]T$, and similarly $[T^{*2}, T] = (1 + \alpha^2)[T^*, T]T^*$, which proves (5.4). Since, in (5.1), $A \geq 0$ and $N(A) = \{0\}$, it follows from (5.4) that we may take

$$V := (1 + \alpha^2)[T^*, T]^{\frac{1}{2}}\left(\frac{\lambda}{\alpha^2}T + T^*\right).$$

Then a straightforward calculation shows that

$$\begin{aligned} C - V^*V &= (1 + \lambda^2)[T^{*2}, T^2] + \lambda\left([T^{*3}, T] + [T^*, T^3] + T^*[T^*, T]T^* + T[T^*, T]T\right) \\ &\quad - (1 + \alpha^2)^2\left(\frac{\lambda}{\alpha^2}T^* + T\right)[T^*, T]\left(\frac{\lambda}{\alpha^2}T + T^*\right) \\ &= (1 + \lambda^2)[T^{*2}, T^2] - \frac{(1 + \alpha^2)^2}{\alpha^4}\left(\lambda^2T^*[T^*, T]T + \alpha^4T[T^*, T]T^*\right) + \lambda(Q + Q^*), \end{aligned}$$

where

$$Q := [T^*, T^3] - \left(\alpha^2 + 1 + \frac{1}{\alpha^2}\right)T[T^*, T]T.$$

Observe that both $[T^*, T^3]$ and $T[T^*, T]T$ are unilateral weighted shifts of multiplicity 2. Thus to determine Q , it suffices to check the $(n + 2, n)$ -entries. Now

$$\begin{aligned} (Qe_n, e_{n+2}) &= ([T^*, T^3]e_n, e_{n+2}) - \left(\alpha^2 + 1 + \frac{1}{\alpha^2}\right)(T[T^*, T]Te_n, e_{n+2}) \\ &= \beta_n\beta_{n+1}(\beta_{n+2}^2 - \beta_{n-1}^2) - \left(\alpha^2 + 1 + \frac{1}{\alpha^2}\right)\beta_n\beta_{n+1}(\beta_{n+1}^2 - \beta_n^2) \\ &= \beta_n\beta_{n+1}\left(\alpha^{2n+4} + \alpha^{2n+2} + \alpha^{2n} - \left(\alpha^2 + 1 + \frac{1}{\alpha^2}\right)\alpha^{2n+2}\right) \\ &= 0, \end{aligned}$$

which implies $Q \equiv 0$. Therefore,

$$C - V^*V = (1 + \lambda^2)[T^{*2}, T^2] - \left(1 + \frac{1}{\alpha^2}\right)^2\left(\lambda^2T^*[T^*, T]T + \alpha^4T[T^*, T]T^*\right).$$

Observe that $[T^{*2}, T^2]$, $T^*[T^*, T]T$, and $T[T^*, T]T^*$ are all diagonal. Thus to determine $C - V^*V$, it suffices to check the (n, n) -entries. Now

$$\begin{aligned}
& ((C - V^*V)e_n, e_n) \\
&= (1 + \lambda^2)([T^{*2}, T^2]e_n, e_n) - \left(1 + \frac{1}{\alpha^2}\right)^2 (\lambda^2(T^*[T^*, T]Te_n, e_n) + \alpha^4(T[T^*, T]T^*e_n, e_n)) \\
&= (1 + \lambda^2)(\beta_{n+1}^2\beta_n^2 - \beta_{n-1}^2\beta_{n-2}^2) - \left(1 + \frac{1}{\alpha^2}\right)^2 (\lambda^2\beta_n^2(\beta_{n+1}^2 - \beta_n^2) + \alpha^4\beta_{n-1}^2(\beta_{n-1}^2 - \beta_{n-2}^2)) \\
&= (1 + \lambda^2) \left((\alpha^{2n-2} + \alpha^{2n}) \sum_{j=1}^{n-1} \alpha^{2j} + (\alpha^{2n} + \alpha^{2n+2}) \sum_{j=0}^n \alpha^{2j} \right) \\
&\quad - \left(1 + \frac{1}{\alpha^2}\right)^2 \left(\lambda^2\alpha^{2n+2} \sum_{j=0}^n \alpha^{2j} + \alpha^4\alpha^{2n-2} \sum_{j=0}^{n-1} \alpha^{2j} \right) \\
&= \left(1 + \frac{1}{\alpha^2}\right)^2 \alpha^{4n+2} - (1 + \lambda^2)\alpha^{4n-2}(1 + \alpha^2) \\
&= (1 + \alpha^2)(\alpha^2 - \lambda^2)\alpha^{4n-2} \\
&= \frac{(1 + \alpha^2)(\alpha^2 - \lambda^2)}{\alpha^2} (\beta_n^2 - \beta_{n-1}^2)^2 \\
&= \frac{(1 + \alpha^2)(\alpha^2 - \lambda^2)}{\alpha^2} ([T^*, T]e_n, e_n)^2,
\end{aligned}$$

which implies

$$C - V^*V = \frac{(1 + \alpha^2)(\alpha^2 - \lambda^2)}{\alpha^2} [T^*, T]^2.$$

Therefore $C \geq V^*V$ if and only if $0 \leq \lambda \leq \alpha$, and hence S_λ is 2-hyponormal if and only if $0 \leq \lambda \leq \alpha$. This completes the proof. \square

In the following theorem, the proofs of the statements (i) and (ii) are given in [Cow1, Theorem 2.4].

Theorem 6. *Let $0 < \alpha < 1$ and let ψ be the conformal map of the unit disk onto the interior of the ellipse with vertices $\pm(1 + \alpha)i$ and passing through $\pm(1 - \alpha)$. Let $\varphi = \psi + \lambda\bar{\psi}$ and let T_φ be the corresponding Toeplitz operator on H^2 . Then*

- (i) T_φ is hyponormal if and only if λ is in the closed unit disk $|\lambda| \leq 1$.
- (ii) T_φ is subnormal if and only if $\lambda = \alpha$ or λ is in the circle $\left| \lambda - \frac{\alpha(1 - \alpha^{2k})}{1 - \alpha^{2k+2}} \right| = \frac{\alpha^k(1 - \alpha^2)}{1 - \alpha^{2k+2}}$ for $k = 0, 1, 2, \dots$.
- (iii) T_φ is 2-hyponormal if and only if λ is in the unit circle $|\lambda| = 1$ or in the closed disk $\left| \lambda - \frac{\alpha}{1 + \alpha^2} \right| \leq \frac{\alpha}{1 + \alpha^2}$.

Proof. It was shown in [CoL] that $T_{\psi + \alpha\bar{\psi}}$ is unitarily equivalent to $(1 - \alpha^2)^{\frac{3}{2}}T$, where T is the weighted shift in Theorem 5. Thus T_ψ is unitarily equivalent to $(1 - \alpha^2)^{\frac{1}{2}}(T - \alpha T^*)$,

so T_φ is unitarily equivalent to

$$(1 - \alpha^2)^{\frac{1}{2}}(1 - \lambda\alpha)(T + \frac{\lambda - \alpha}{1 - \lambda\alpha}T^*) \quad (\text{cf. [Cow1, Theorem 2.4]}),$$

applying Theorem 5 with $\frac{\lambda - \alpha}{1 - \lambda\alpha}$ in place of λ . Now, for $k = 0, 1, 2, \dots$,

$$\begin{aligned} \left| \frac{\lambda - \alpha}{1 - \lambda\alpha} \right| \leq \alpha^k &\iff |\lambda - \alpha|^2 \leq \alpha^{2k}|1 - \lambda\alpha|^2 \\ &\iff |\lambda|^2 - \frac{\alpha(1 - \alpha^{2k})}{1 - \alpha^{2k+2}}(\lambda + \bar{\lambda}) + \frac{\alpha^2 - \alpha^{2k}}{1 - \alpha^{2k+2}} \leq 0 \\ &\iff \left| \lambda - \frac{\alpha(1 - \alpha^{2k})}{1 - \alpha^{2k+2}} \right| \leq \frac{\alpha^k(1 - \alpha^2)}{1 - \alpha^{2k+2}}. \end{aligned}$$

If $k = 0$ then $\left| \frac{\lambda - \alpha}{1 - \lambda\alpha} \right| \leq 1 \iff |\lambda| \leq 1$. If $k = 1$ then $\left| \frac{\lambda - \alpha}{1 - \lambda\alpha} \right| \leq \alpha \iff \left| \lambda - \frac{\alpha}{1 + \alpha^2} \right| \leq \frac{\alpha}{1 + \alpha^2}$. This completes the proof. \square

A moment's reflection reveals that the circles in Theorem 6 (ii) form a nested sequence in the sense of their convex hulls.

Corollary 7. *In Theorem 6, if λ lies in the open annulus between the two circles*

$$\left| \lambda - \frac{\alpha}{1 + \alpha^2} \right| = \frac{\alpha}{1 + \alpha^2} \quad \text{and} \quad \left| \lambda - \frac{\alpha(1 - \alpha^4)}{1 - \alpha^6} \right| = \frac{\alpha^2(1 - \alpha^2)}{1 - \alpha^6}$$

then the corresponding Toeplitz operator T_φ is 2-hyponormal but not subnormal.

Now we would like to pose the following conjecture.

Conjecture A. *In Theorem 6, we have:*

- (i) T_φ is quadratically hyponormal if and only if T_φ is 2-hyponormal;
- (ii) T_φ is k -hyponormal if and only if λ is in the circle $\left| \lambda - \frac{\alpha(1 - \alpha^{2j})}{1 - \alpha^{2j+2}} \right| = \frac{\alpha^j(1 - \alpha^2)}{1 - \alpha^{2j+2}}$ for $j = 0, \dots, k - 2$ or in the closed disk $\left| \lambda - \frac{\alpha(1 - \alpha^{2(k-1)})}{1 - \alpha^{2k}} \right| \leq \frac{\alpha^{k-1}(1 - \alpha^2)}{1 - \alpha^{2k}}$.

In a recent preprint, C. Gu [Gu] has announced a proof of part (ii) of Conjecture A, in the context of extending our results to $k \geq 3$. His techniques are different from ours, and seem to exploit a special case of Smul'jan's Theorem (see (5.3) above). However, we have been unable to verify his proof; concretely, we do not follow his beginning argument in the proof of [Gu, Theorem 3.3], using [Gu, Lemma 2.6].

In spite of Theorem 6, it seems to be interesting to consider the following problem:

Which 2-hyponormal Toeplitz operators are subnormal?

The first inquiry involves the self-commutator. Subnormal operators with finite rank self-commutators have been studied by many authors ([Ale], [McCY], [Mor], [OTT], [Xi1],

[Xi2]). In 1975, I. Amemiya, T. Ito and T. Wong [AIW] showed that if T_φ is a subnormal Toeplitz operator with rank-one self-commutator then φ is a linear function of a Blaschke product of degree 1. More generally, B. Morrel [Mor] showed that a pure subnormal operator with rank-one self-commutator is unitarily equivalent to a linear function of the unilateral shift. Very recently, in [CuL2], it was shown that every pure 2-hyponormal operator with rank-one self-commutator is a linear function of the unilateral shift. On the other hand, J. McCarthy and L. Yang [McCY] have classified all rationally cyclic subnormal operators with finite rank self-commutators. However it is still open which are the pure subnormal operators with finite rank self-commutator. Related to this, in [CuL3] we formulated the following:

Question B. *If T_φ is a 2-hyponormal Toeplitz operator with nonzero finite rank self-commutator, does it follow that T_φ is analytic ?*

In fact, it remains still open even whether subnormal Toeplitz operators with finite rank self-commutator are normal. As a strategy to answer to Question B we would like to pose the following conjecture.

Conjecture B. *If T_φ is a 2-hyponormal Toeplitz operator with finite rank self-commutator then*

$$\dim (\text{cl } H_{\bar{\varphi}}(\ker [T_\varphi^*, T_\varphi]))^\perp \leq \dim (\text{cl } H_\varphi(\ker [T_\varphi^*, T_\varphi]))^\perp .$$

If $\ker [T_\varphi^*, T_\varphi] = qH^2$ for some inner function q , then Conjecture B is true: indeed, if k is a function in $\mathcal{E}(\varphi)$ then

$$H_\varphi(\ker [T_\varphi^*, T_\varphi]) = H_{k\bar{\varphi}}(qH^2) = H_{\bar{\varphi}}T_k(qH^2) \subseteq H_{\bar{\varphi}}(qH^2) = H_{\bar{\varphi}}(\ker [T_\varphi^*, T_\varphi]),$$

and hence $(\text{cl } H_{\bar{\varphi}}(\ker [T_\varphi^*, T_\varphi]))^\perp \subseteq (\text{cl } H_\varphi(\ker [T_\varphi^*, T_\varphi]))^\perp$, which implies that Conjecture A is true.

We now have:

Theorem 8. *Suppose that Conjecture B is true. If T_φ is a 2-hyponormal Toeplitz operator with finite rank self-commutator then T_φ is normal or analytic.*

Proof. If φ or $\bar{\varphi}$ is of bounded type then the result follows at once from Theorem 4 with no restriction on the self-commutator. Thus we suppose that φ and $\bar{\varphi}$ both are not of bounded type. Suppose φ is not analytic and T_φ is a hyponormal operator with finite rank self-commutator. It suffices to show that T_φ is normal. By an argument of [Abr, Lemmas 3 and 4] we have that $\ker H_\varphi = \ker H_{\bar{\varphi}} = \{0\}$, and $\text{ran } H_\varphi$ and $\text{ran } H_{\bar{\varphi}}$ are both dense in H^2 . Observe (cf. [Abr, Lemma 1]) that for $h \in H^2$,

$$(8.1) \quad (h, [T_\varphi^*, T_\varphi]h) = \|H_{\bar{\varphi}}h\|^2 - \|H_\varphi h\|^2.$$

Since T_φ is hyponormal it follows that

$$(8.2) \quad \|H_\varphi h\| \leq \|H_{\bar{\varphi}}h\| \quad (h \in H^2).$$

Define an operator S on $\text{ran } H_{\bar{\varphi}}$ by

$$S(H_{\bar{\varphi}}h) = H_{\varphi}h.$$

Then S is well defined and $\|S\| \leq 1$ by (8.2), so S has an extension to H^2 since $\text{ran } H_{\bar{\varphi}}$ is dense in H^2 . In [Cow3, Proof of Theorem 1] it was shown that

- (i) S is a contraction on H^2 ;
- (ii) S is a co-analytic Toeplitz operator, say $S := T_{\tilde{k}}$ with $k \in H^{\infty}$;
- (iii) $T_{\tilde{k}}H_{\bar{\varphi}} = H_{\varphi}$;
- (iv) $\tilde{k} \in \mathcal{E}(\varphi)$, where $\tilde{k} = \overline{k(\bar{z})}$.

Since $[T_{\varphi}^*, T_{\varphi}]$ is of finite rank, we have that $\ker [T_{\varphi}^*, T_{\varphi}]$ has finite co-dimension. Also by (8.1) we have that

$$\|H_{\bar{\varphi}}h\| = \|H_{\varphi}h\| \quad \text{for all } h \in \ker [T_{\varphi}^*, T_{\varphi}].$$

Thus the restriction of $T_{\tilde{k}}$ to $\text{cl } H_{\bar{\varphi}}(\ker [T_{\varphi}^*, T_{\varphi}])$ is an isometry. Now put

$$M := \text{cl } H_{\bar{\varphi}}(\ker [T_{\varphi}^*, T_{\varphi}]) \quad \text{and} \quad N := \text{cl } H_{\varphi}(\ker [T_{\varphi}^*, T_{\varphi}]).$$

Since both $H_{\bar{\varphi}}$ and H_{φ} are one-one and have dense ranges it follows that M^{\perp} and N^{\perp} are finite-dimensional. If Conjecture B is true then we have

$$\dim M^{\perp} \leq \dim N^{\perp}.$$

Since $T_{\tilde{k}}|_M$ is an isometry, we can see that $T_k T_{\tilde{k}} = I + K$, where K is a finite rank operator. Then by Douglas's Theorem, which states that if $T_{\varphi_1} T_{\varphi_2} - T_{\varphi_3}$ is compact then $\varphi_1 \varphi_2 = \varphi_3$, we have that $|k|^2 = 1$, so that T_k is an isometry because $T_{\tilde{k}}$ is analytic. Write $T_{\tilde{k}}$ as the following 2×2 operator matrix:

$$T_{\tilde{k}} = \begin{pmatrix} A & B \\ C & D \end{pmatrix} : \begin{pmatrix} M \\ M^{\perp} \end{pmatrix} \longrightarrow \begin{pmatrix} N \\ N^{\perp} \end{pmatrix},$$

where A is an isometry. Since $T_{\tilde{k}}$ is a contraction, it follows that $C = 0$. Also since T_k is an isometry, we have

$$T_{\tilde{k}} T_k = \begin{pmatrix} A & B \\ 0 & D \end{pmatrix} \begin{pmatrix} A^* & 0 \\ B^* & D^* \end{pmatrix} = \begin{pmatrix} AA^* + BB^* & BD^* \\ DB^* & DD^* \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix},$$

so

$$\begin{cases} AA^* + BB^* = 1 \\ BD^* = 0 \\ DD^* = 1. \end{cases}$$

Since $D^* : N^{\perp} \rightarrow M^{\perp}$ is an isometry, it follows that $\dim M^{\perp} = \dim N^{\perp}$, so that D^* is unitary. Thus we must have that $B = 0$ and in turn, $AA^* = 1$. This forces A to be unitary, so that T_k is unitary. Therefore k is a constant of modulus 1, and hence so is \tilde{k} . But since $\tilde{k} \in \mathcal{E}(\varphi)$, it follows that φ is of the form $\varphi = \bar{f} + e^{i\theta} f$ for some $f \in H^{\infty}$ and $\theta \in [0, 2\pi)$, which implies that T_{φ} is normal. This completes the proof. \square

The core of the proof of Theorem 8 is that if φ is not of bounded type for which T_φ is a 2-hyponormal Toeplitz operator with nonzero finite rank self-commutator then T_φ is analytic. One might expect that this is true with “hyponormal” in place of “2-hyponormal,” but this is not the case. To see this let ψ be the conformal map in Theorem 3. Then $\varphi \equiv \bar{\psi} + z\psi$ is not of bounded type because, in Theorem 3, $\bar{\psi} + \alpha\psi$ is not of bounded type, so that $\{0\} \neq \ker H_{\bar{\psi} + \alpha\psi} = \ker H_{\bar{\psi}} = \ker H_\varphi$, and hence φ is not of bounded type by [Abr, Lemma 3]. Observe that $\varphi - z\bar{\varphi} \in H^\infty$ which, by Cowen’s Theorem, says that T_φ is hyponormal. But since

$$\begin{aligned} [T_\varphi^*, T_\varphi] &= (T_\psi + T_{\bar{z}}T_{\bar{\psi}})(T_{\bar{\psi}} + T_zT_\psi) - (T_{\bar{\psi}} + T_zT_\psi)(T_\psi + T_{\bar{z}}T_{\bar{\psi}}) \\ &= T_\psi T_{\bar{\psi}} - T_\psi T_z T_{\bar{z}} T_{\bar{\psi}} = T_\psi(1 - T_z T_{\bar{z}})T_{\bar{\psi}}, \end{aligned}$$

it follows that $\text{rank}[T_\varphi^*, T_\varphi] = 1$.
